Abstract

We describes the codes for the manuscript "Traveling vegetation-herbivore waves may sustain ecosystems threatened by droughts and population growth" by Singha et al. The methods include numerical continuation using pde2path.

1 Brief description of the model

In [SUM24] we consider a spatially explicit model that describes the coupled dynamics of vegetation, soil water, and herbivores in dryland ecosystems. The model captures two critical stressors—limited water availability and herbivory—and incorporates feedback mechanisms that can give rise to spatial self-organization. In particular, the model accounts for a behavioral component of herbivore movement, referred to as "vegetaxis," in which herbivores are attracted to denser vegetation patches. This feature plays a crucial role in shaping vegetation—herbivore patterns.

Let B(x,t), W(x,t), and H(x,t) represent the vegetation biomass density, soil water content, and herbivore biomass density, respectively, at spatial location x and time t. The governing equations are:

$$\partial_t B = \Lambda B W (1 + EB)^2 \left(1 - \frac{B}{K_B} \right) - M_B B + D_B \nabla^2 B - G(B) H,$$

$$\partial_t W = P - \frac{NW}{1 + RB/K_B} - \Gamma B W (1 + EB)^2 + D_W \nabla^2 W,$$

$$\partial_t H = -M_H H + A G(B) H \left(1 - \frac{H}{K_H} \right) - \nabla \cdot \mathbf{J}_H.$$

Vegetation growth depends on local water availability and is enhanced by root development, modeled through the nonlinear term $\Lambda BW(1+EB)^2$. Growth is also limited by saturation effects and competition, captured by the factor $1-B/K_B$. Vegetation biomass decreases due to natural mortality at rate M_B and through consumption by herbivores, where the consumption rate G(B) follows a saturating function:

$$G(B) = \frac{\alpha B}{\beta + B},$$

with α representing the maximum per capita consumption rate and β the biomass at which half-maximum consumption occurs.

The soil water balance includes a constant precipitation input P, reduced by evaporation, which is itself mitigated by shading from vegetation $(NW/(1 + RB/K_B))$. Plants extract water from the

soil via a nonlinear uptake term proportional to $BW(1+EB)^2$, while water diffuses laterally at a rate D_W .

Herbivores grow by consuming vegetation, reproducing at a rate proportional to the product G(B)H, moderated by density dependence via the factor $1 - H/K_H$. Herbivore losses are due to natural mortality at rate M_H and spatial redistribution. Movement is governed by the flux term:

$$\mathbf{J}_H = -D_R(B)\nabla H + HD_V(B)\nabla B,$$

where $D_R(B)$ describes biomass-dependent random movement:

$$D_R(B) = D_{HH} \frac{H\xi^2}{\xi^2 + B^2},$$

and $D_V(B)$ describes biased movement up vegetation gradients (vegetaxis):

$$D_V(B) = D_{HB} \frac{B}{\kappa + B}.$$

In this framework, herbivores tend to move more rapidly in bare-soil regions and slow down as they approach vegetation, while also being drawn toward denser patches. This behavior mimics an exploitation strategy, allowing herbivores to efficiently locate and graze on vegetation.

This system of equations can give rise to a rich variety of spatial and temporal patterns, including stationary vegetation stripes, localized herbivore aggregations, and traveling vegetation—herbivore waves. These emergent behaviors are critical for understanding the resilience of dryland ecosystems under increasing stress due to climate change and population-driven grazing pressure.

All scripts can simply be run by calling them from the Matlab command line; however, we strongly recommend running them in cell-mode from the Matlab editor, to see the results of individual cells and commands. For easy online use, the folder bwhcont contain cmds.m with cell blocks beginning with a brief description in each block.

The folder **bwhcont** contains all the necessary files to reproduce the bifurcation diagrams presented in the manuscript (see Table 1 for an overview). Before making any modifications, we recommend consulting the relevant documentation or references [Uec21], [Uec25] to become familiar with the **pde2path** command structure and workflow.

Table 1: Scripts and functions in bwhcont/

file	purpose, remarks
	purpose, remarks
cmds1	continuation of homogeneous branches and branch switching to and contin-
	uation of Turing branches and travelling wave branches; to cont. speed
cmds2	branch, fold and hopf point continuation
cmdsplot	plot commands for the bifurcation diagrams
cmdsdatext	to extract data to text files
bwhinit	Initialisation of problem struct p with the required parameter values; gener-
	ates the FEM matrices by calling oosetfemops; sets the pde2path param-
	eters according the requirement of the problem
oosetfemops	creates the mass matrix M and the laplacian K for periodic boundary con-
	dition
nodalf	kinetic terms without the spatial derivatives
sG	right hand side of the PDE with the spatial terms in the moving co-ordinate
	system
hobrax	mod of library function hobra
twswibrax	mod of library function twswibra
qf1, qf1der, qjac	standard phase condition for translational invariance in 'x'

The function bwhinit.m initialises the problem, with the inputs the domain size 1x, the number of discretization points nx, the model parameter par, an initial homogeneous solution [B, W, H], and the output folder name 'bwh'. The basic procedure is to use p = stanparam to general a problem structure with standard values of numerical parameters and control switches to obtain the bifurcation branch. The default value of are often overwritten to make it suitable for the problem description, for example we have modified hobra.m to hobrax.m as function handler for output. The function oosetfemops.m creates the necessary finite element matrices such as stiffness matrix in p.mat.K and the mass matrix p.mat.M appropriate for periodic boundary condition (see Listing 1).

```
1 function p=bwinit(lx,nx,par,varargin)
 2 p=stanparam; % initialize fields with defaults, then overwrite some:
 3 p.nc.neq=3; p.sw.sfem=-1;
 4 p.fuha.outfu=@hobrax; % mod of llibrary function hobra
 5 p.pdeo=stanpdeo1D(lx,2*lx/nx); p.vol=2*lx; % standard 1D PDE object
 6 p.np=p.pdeo.grid.nPoints; p.nu=p.np*p.nc.neq; % # PDE unknowns
 7 p.nc.neig=30; % #eigenvalues to compute, and reference point for this
8 p.sol.xi=1/p.nu; p.file.smod=1; p.sw.para=2; p.sw.foldcheck=1;

29 % Bare soil solution branch (BS)
30 p=cont(p,1000); %continuation with number of steps
```

Listing 3: /Users/joydeepsingha/Documents/Matlab/bwhcont/cmds1.m, init and cont of bare soil.

From the first branch point of the BS branch, we continue the UV branch (see Listing 4).

```
31 %% branch switching to uniform vegetation solution branch without herbivore (UV) 32 % arguments: input dir, branch point no, output dir, initial stepsize 33 p=swibra('bwh/BS','bpt1','bwh/UV',0.05); pause; % pause to inspect kernel in Fig.6 34 p.nc.dsmax=1.0; p=cont(p,100000);
```

Listing 4: /bwhcont/cmds1.m continued; swibra to UV; use firstnumber and label, see source

From the UV we then continue to the UH branch (see listing 5).

```
35 %% Uniform solution branch with vegetation and herbivore (UH) using swibra command 36 p=swibra('bwh/UV','bpt2','bwh/UH',-0.01); p.nc.dsmax=5.0; 37 p.file.smod=20; p=cont(p,10000);
```

Listing 5: /bwhcont/cmds1.m continued; swibra to UH;

Here if swibra does not work, we can manually switch to the UH branch by using loadp jump from the branch point to UH (see listing 6).

Listing 6: /bwhcont/cmds1.m continued; manuall switching to UH;

At low precipitation, UV has a turing bifurcation point. Using swibra the SP_0 branch is obtained. Here also use the phase condition (see listing 7).

```
45 %% stationary periodic solution branch of vegetation without herbivore (SP0)
46 p=swibra('bwh/UV','bpt4','bwh/SP0',-0.1); pause;
47 p.sw.bifcheck=0; p.nc.dsmax=0.1; p=cont(p,20);pause;
48 p.nc.nq=1; p.nc.ilam=[6,20]; %phase condition on and adding speed as another bifurcation parameter
49 p.fuha.qf=@qf1; p.fuha.qfder=@qf1der; %standard phase condition and derivative
50 p.sw.qjac=1; %phase condition jacobian
51 p.sw.bifcheck=2; p=cont(p,5000);
```

Listing 7: /bwhcont/cmds1.m continued; swibra to SP_0 ;

This SP_0 branch looses stability to SP_H which is accessed again using swibra from the corresponding branch point on SP_0 (see listing 8).

```
52 %% stationary periodic solution branch vegetation and herbivore (SPH)
53 p=swibra('bwh/SPO','bpt3','bwh/SPH',-0.1); pause;
54 p.nc.tol=1e-8; p.nc.dsmax=0.1; p=cont(p,200);
```

Listing 8: /bwhcont/cmds1.m continued; swibra to SP_H ;

 SP_H quickly looses stability from which the TW branch continued (see listing 9).

```
55 %% travelling solution branch of both vegetation and herbivore (TW at low P)
56 % DRIFT bif., hence swibra, not twswibra
57 p=swibra('bwh/SPH','bpt1','bwh/TW',0.1); pause;
58 p.nc.tol=1e-5;p.nc.dsmax=1.0;
59 p.sw.bifcheck=2; p=cont(p,100000);
```

Listing 9: /bwhcont/cmds1.m continued; swibra to TW at low P;

On the UH branch, these solutions loose stability in Hopf bifurcation. This travelling wave branch is found using twswibrax (see listing 10).

```
60 %% travelling solution branch from UH branch (TW at high P)
61 kwnr=1.0; %guess for spatial wave number
62 aux.z=[1 -1i]; %auxilary arg for twswibrax, this comb of guesses of z1 and z2 works well
       for hp point on UH
63 hp='hpt1'; outb='bwh/TW'; %hopf point number;output directory
64 p=twswibrax('bwh/UH',hp,20,kwnr,outb,aux); %branch switching from hopf point to
       travelling wave branch
65 \text{ p.sol.ds} = -0.1; \text{ p.nc.dsmax} = 1;
66 p.u0(1:p.nu)=p.tau(1:p.nu);
                                    %reference profile
67 p.u0=p.u0'; p.u0x=p.mat.Kx*p.u0; % setting PC
68 plotsolu(p,p.u0x,1,3,1);
69 p.u(1:p.nu)=p.u(1:p.nu)+0.01*p.tau(1:p.nu);
70 p.nc.tol=1e-6; p.nc.nq=1;
71 p.nc.ilam=[6;20]; p.fuha.qf=@qf; p.sw.qjac=1; p.fuha.qfder=@qjac;
72 p.sw.bifcheck=2; pause;
73 p.nc.dsmax=0.01; p=cont(p,10);
                                    %to check speed
74 \text{ par=getaux(p); par(20)}
```

Listing 10: /bwhcont/cmds1.m continued; twswibrax to the TW branch at high P;

Using the above settings for the pde2path switches and parameters values given already in the beginning of bwhcont/cmds.m, the following complete bifurcation diagram (see Fig. 1) can be obtained,

All of the bifurcation diagrams in [SUM24] (Figs. 3, 5, 6, 7, 14, 16) were obtained using the above for different values of parameters. To generate Fig. 16, low values of p.sol.ds and p.nc.dsmin on the order of 10^{-4} were used, as they were necessary to zoom in on a narrow range of P. For a few customisation advantage we use pyplot (script not provided but available upon request) after extracting the data in a text file (see listing 11).

```
1 %% solution branches
                            %array size depends on the number of points in the dir
 2 P=zeros(110,3);

20 for i=1:27;
```

```
21
      pt=['bwh/BS' ...
           '/pt' mat2str(0+i*1)]; tmp=load(pt);tmpp=tmp.p; %change input directory
22
      accordingly
23
      P(i,1) = tmpp.u(tmpp.nu + 6);
24
25
      P(i,2) = tmpp.u(tmpp.nu + 13);
26
      P(i,3)=tmpp.sol.ineg;
27
28 end
29 ptr=fopen('bwh/UV2bpcont.txt','w');
                                               %change output directory accordingly
30 fprintf(ptr,'%e\t%e\t%e\n',P');
31 fclose(ptr);
```

Listing 14: /bwhcont/cmdsdatext.m continued; speed vs $D_H B$ plot data extraction;

The phase diagrams in Figs. 9.a and 10.a in [SUM24] were mostly obtained using branch point continuation method in pde2path (see listings 15, 16, 17 for branch, fold and hopf point continuation respectively.). We advise caution for these continuations whenever H is non-zero or branch points are nearby as the p.nc.ntol needs to adjusted during continuation. Whenever there are convergence error the boundaries between these stable solutions are completed manually from the bifurcation diagram. We also advise that the boundary of the phase diagram should be checked always using direct numerical simulation whether above and below the boundary the desired solutions are obtained.

```
